

# Experiment 3: Crypto Lab – Secret-Key Encryption

Name: Deep Nayak UID: 2019130045 TE COMPS

## OBJECTIVE

The learning objective of this lab is for students to get familiar with the concepts in the secret-key encryption. After finishing the lab, students should be able to gain a first-hand experience on encryption algorithms, encryption modes, paddings, and initial vector (IV). Moreover, students will be able to use tools and write programs to encrypt/decrypt messages.

## LAB TASKS

### Task 1: Encryption using different ciphers and modes

In this task, we will play with various encryption algorithms and modes. You can use the following openssl enc command to encrypt/decrypt a file. To see the manuals, you can type man openssl and man enc.

Encryption using different cipher algorithms:

The plain text that is encrypted in every scenario is as follows:

```
plain_text_1.txt ✘  
CSS-Lab-Deep-Nayak > Experiment 3 > plain_text_1.txt  
1 Base to all engaged units.  
2 Eagle is going to attack land of the rising sun with deadliest weapons in existence.  
3 All units are ordered to stand down and stay on alert.  
4 In case of any new information, encrypt the same and send it via secure channel.  
5 Destroy this message once it has served its purpose.  
6 Over and Out.|
```

Fig 1.1

### 1. Encryption using ARIA-128-CBC

Encrypted Text:

```

Fig 1.19

### Observations:

1. Camellia is Japan's first 128 bit block cipher. In terms of security it is equivalent or even more secure than triple DES. A single DES encryption is vulnerable to brute force attacks however since Camellia matches the standards of triple DES and AES it is very secure. Encryption processing and decryption processing are achieved using the same structure in Camellia, hence, it exhibits superior performance particularly in IC cards that have a low capacity memory or compact hardware. It has either 18 rounds (when using 128-bit keys) or 24 rounds (when using 192- or 256-bit keys)
2. Aria is also a 128 bit block cipher developed by Korean scientists. It uses a substitution-permutation network (SPN) structure based on AES. ARIA uses two 8×8-bit S-boxes and their inverses in alternate rounds. The number of rounds is 12, 14, or 16, depending on the key size
3. AES comprises a series of linked operations, some of which involve replacing inputs by specific outputs (substitutions) and others involve shuffling bits around (permutations). AES performs all its computations on bytes rather than bits. Hence, AES treats the 128 bits of a plaintext block as 16 bytes. AES uses 10 rounds for 128-bit keys, 12 rounds for 192-bit keys and 14 rounds for 256-bit keys.

## Task 2: Encryption Mode – ECB vs. CBC

The file pic original.bmp contains a simple picture. We would like to encrypt this picture, so people without the encryption keys cannot know what is in the picture. Please encrypt the file using the ECB (Electronic Code Book) and CBC (Cipher Block Chaining) modes, and then do the following:

1. Let us treat the encrypted picture as a picture, and use a picture viewing software to display it. However, For the .bmp file, the first 54 bytes contain the header information about the picture, we have to set it correctly, so the encrypted file can be treated as a legitimate .bmp file. We will replace the header of the encrypted picture with that of the original picture. You can use the ghex tool to directly modify binary files.
2. Display the encrypted picture using any picture viewing software. Can you derive any useful information about the original picture from the encrypted picture? Please explain your observations.

hex string is too short, padding with zero bytes to length
deep@deep-HP-Pavilion-Gaming-Laptop-15-dk0xxx:~/spit/css/CSS-Lab-Deep-Nayak/Experiment 3/Task 2$ tail -c 556084 temp.bin >> enc2.bmp
deep@deep-HP-Pavilion-Gaming-Laptop-15-dk0xxx:~/spit/css/CSS-Lab-Deep-Nayak/Experiment 3/Task 2$
```

*Fig 2.4*

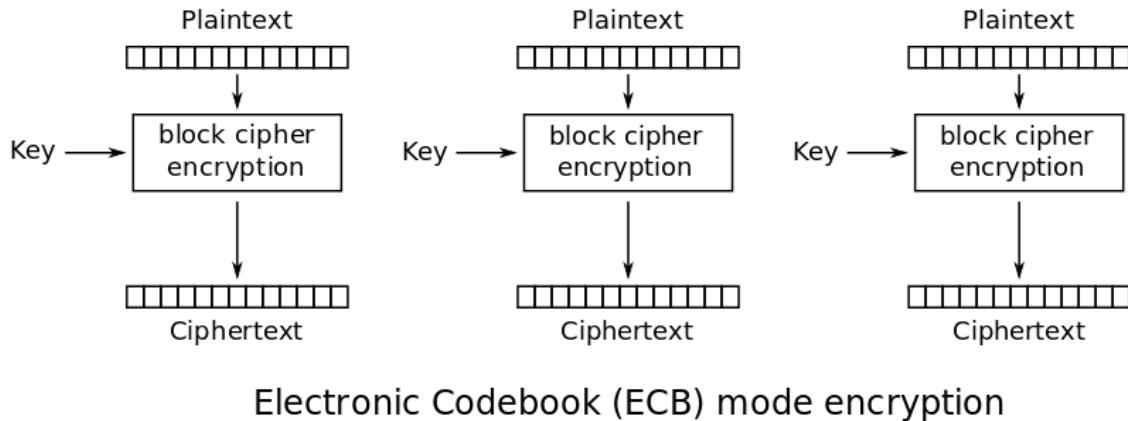

Encrypted image using CBC:

*Fig 2.5*

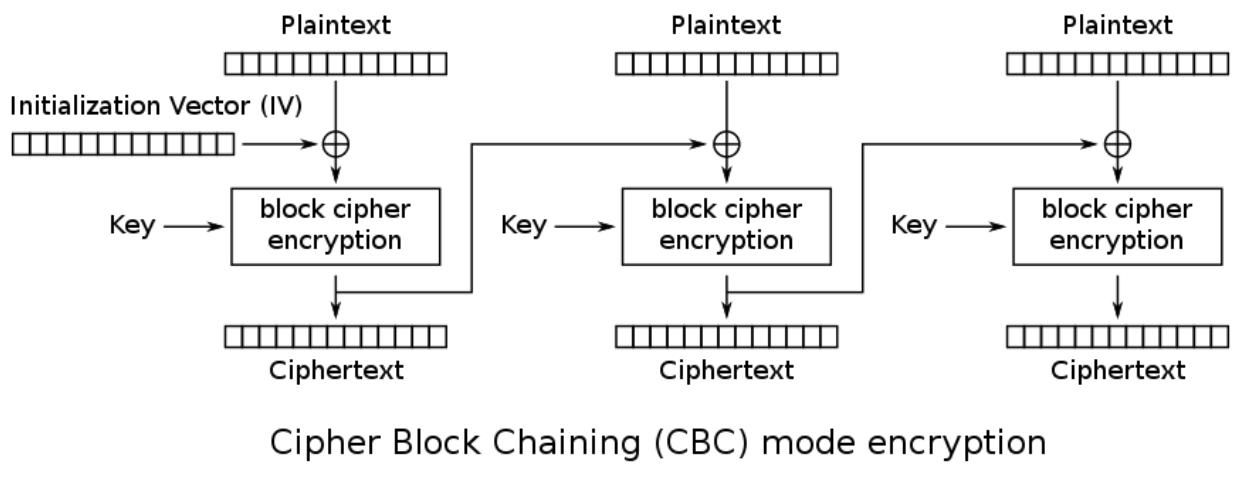

Observations:

1. In ECB, the overall structure of the original image is still maintained in the encrypted image. This means that the original image can be guessed to some extent when ECB is used. This mainly happens because we use the same key on each and every block and get the output for each of them.

**Fig 2.6 | Credits: Wikipedia**

2. In CBC, the overall structure of the original image is not transferred to the encrypted image. This means that it is impossible to guess the original image based on the encrypted image. This mainly happens because in CBC, we XOR every block with the last encrypted block and then encrypt the current block, this helps in breaking patterns in the data and makes it more secure.

**Fig 2.6 | Credits: Wikipedia**

### Task 3: Encryption Mode – Corrupted Cipher Text

To understand the properties of various encryption modes, we would like to do the following exercise:

1. Create a text file that is at least 64 bytes long.
2. Encrypt the file using the AES-128 cipher.
3. Unfortunately, a single bit of the 30th byte in the encrypted file got corrupted. You can achieve this corruption using ghex.
4. Decrypt the corrupted file (encrypted) using the correct key and IV.

Please answer the following questions: (1) How much information can you recover by decrypting the corrupted file, if the encryption mode is ECB, CBC, CFB, or OFB, respectively? Please answer this question before you conduct this task, and then find out whether your answer is correct or wrong after you finish this task. (2) Please explain why. (3) What are the implications of these differences?

```

Fig 3.5

## Observations:

**Fig 3.6 | Credits: Wikipedia**

Since every block cipher is encrypted separately using the key, when one byte is corrupted and then decrypted, it only affects the corresponding block of data while the other blocks of data are unaffected.

## AES-128-CBC

```
deep@deep-HP-Pavilion-Gaming-Laptop-15-dk0xxx:~/spit/css/CSS-Lab-Deep-Nayak/Experiment 3/Task 3$ openssl enc -aes-128-cbc -e -in plain_text_1.txt -out encrypted_cbc.txt -K 00112233445566778899aabccddeff -iv 0102030405060708
hex string is too short, padding with zero bytes to length

```

**Fig 3.9**

### Observation:

**Fig 3.10 | Credits: Wikipedia**

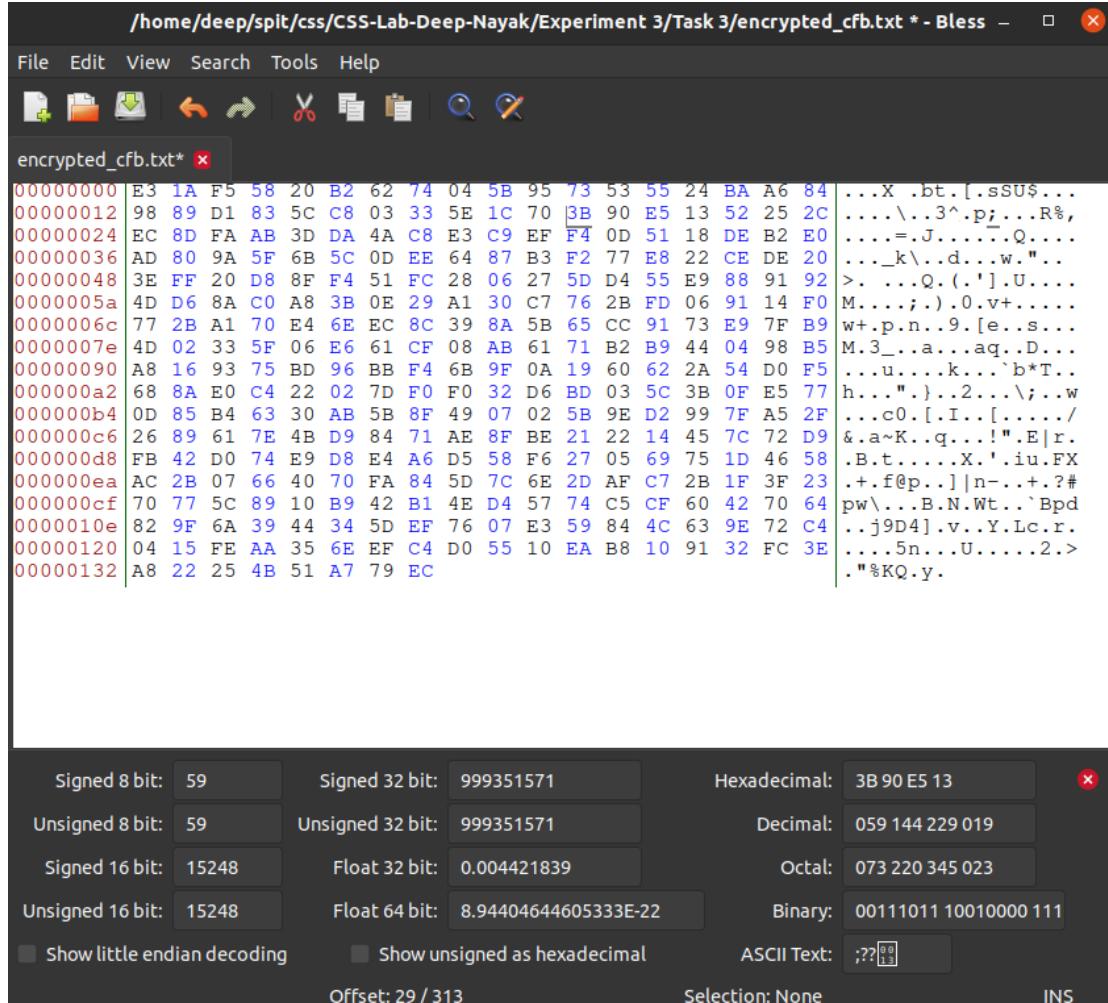

In CBC every encrypted block cipher depends on the previous encrypted block cipher. However while decrypting, we perform XOR on the decrypted block by using the previous cipher text. Hence a one-bit change to the ciphertext causes complete corruption of the corresponding block of plaintext, and inverts the corresponding bit in the following block of plaintext, but the rest of the blocks remain intact.

### AES-128-CFB

```
deep@deep-HP-Pavilion-Gaming-Laptop-15-dk0xxx:~/spit/css/CSS-Lab-Deep-Nayak/Experiment 3/Task 3$ openssl enc -aes-128-cfb -e -in plain_text_1.txt -out encrypted_cfb.txt -K 00112233445566778899aabcccddeeff -iv 0102030405060708
hex string is too short, padding with zero bytes to length
deep@deep-HP-Pavilion-Gaming-Laptop-15-dk0xxx:~/spit/css/CSS-Lab-Deep-Nayak/Experiment 3/Task 3$ bless encrypted cfb.txt
```

**Fig 3.11**

## Corrupting the 30th Byte

**Fig 3.12**

Decrypted text:

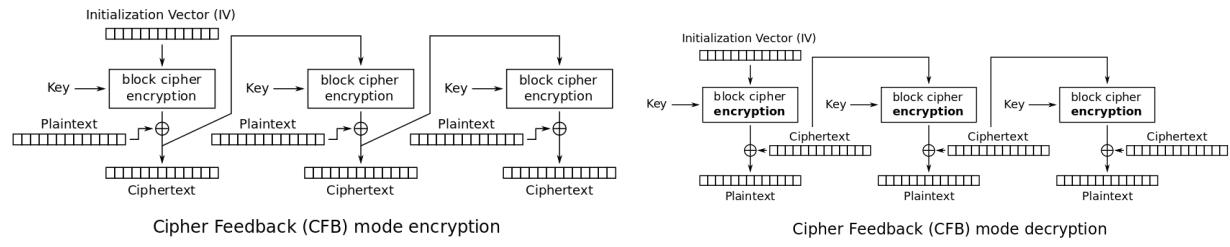

```
deep@deep-HP-Pavilion-Gaming-Laptop-15-dk0xxx:~/spit/css/CSS-Lab-Deep-Nayak/Experiment 3/Task 3$ openssl enc -aes-128-cfb -d -in encrypted_cfb.txt -out decrypted_cfb.txt -K 00112233445566778899aabccddeff -iv 0102030405060708
hex string is too short, padding with zero bytes to length
```

**Fig 3.13**

```

1 Base to all engaged units.
2 Ea(lle:00h0f00T%Wj0 00ack land of the rising sun with deadliest weapons in existence.
3 All units are ordered to stand down and stay on alert.
4 In case of any new information, encrypt the same and send it via secure channel.
5 Destroy this message once it has served its purpose.
6 Over and Out.|
```

**Fig 3.14**

## Observation:

**Fig 3.15 | Credits: Wikipedia**

Loss in CFB is much less as compared to ECB and CBC. This is because the same encryption algorithm is used for decryption and the corrupted cipher text for a block is used for two corresponding blocks hence limiting the damage to two blocks of cipher text.

## AES-128-OFB

```
deep@deep-HP-Pavilion-Gaming-Laptop-15-dk0xxx:~/spit/css/CSS-Lab-Deep-Nayak/Experiment 3/Task 3$ openssl enc -aes-128-ofb -e -in plain_text_1.txt -out encrypted_ofb.txt -K 00112233445566778899aabbcdddeeff -iv 0102030405060708
hex string is too short, padding with zero bytes to length

**Fig 3.18**

### Observation:

**Fig 3.19 | Credits: Wikipedia**

The data lost in OFB is the least as compared to other block cipher modes. This is mainly because flipping a bit in the ciphertext produces a flipped bit in the plaintext at the same location. This property allows many error-correcting codes to function normally even when applied before encryption.

### Task4 : Padding

For block ciphers, when the size of the plain text is not the multiple of the block size, padding may be required. In this task, we will study the padding schemes. Please do the following exercises:

1. The openssl manual says that openssl uses PKCS5 standard for its padding. Please design an experiment to verify this. In particular, use your experiment to figure out the paddings in the AES encryption when the length of the plaintext is 20 octets and 32 octets.
2. Please use ECB, CBC, CFB, and OFB modes to encrypt a file (you can pick any cipher). Please report which modes have paddings and which ones do not. For those that do not need paddings, please explain why.

Original Files:

Small.txt

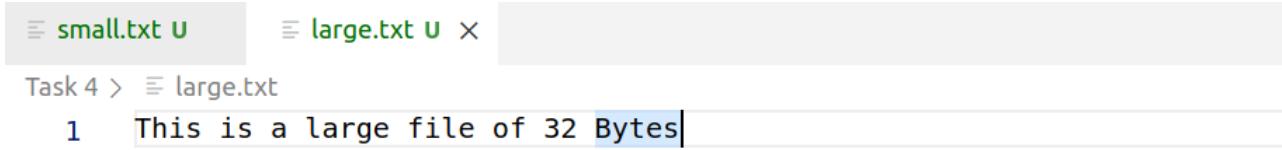

The screenshot shows a terminal window with two tabs: "small.txt" and "large.txt". The "small.txt" tab is active, displaying the text "1 Small file of 20 B .". The "large.txt" tab is visible in the background.

```
Task 4 > small.txt
1 Small file of 20 B .
```

**Fig 4.1**

Large.txt

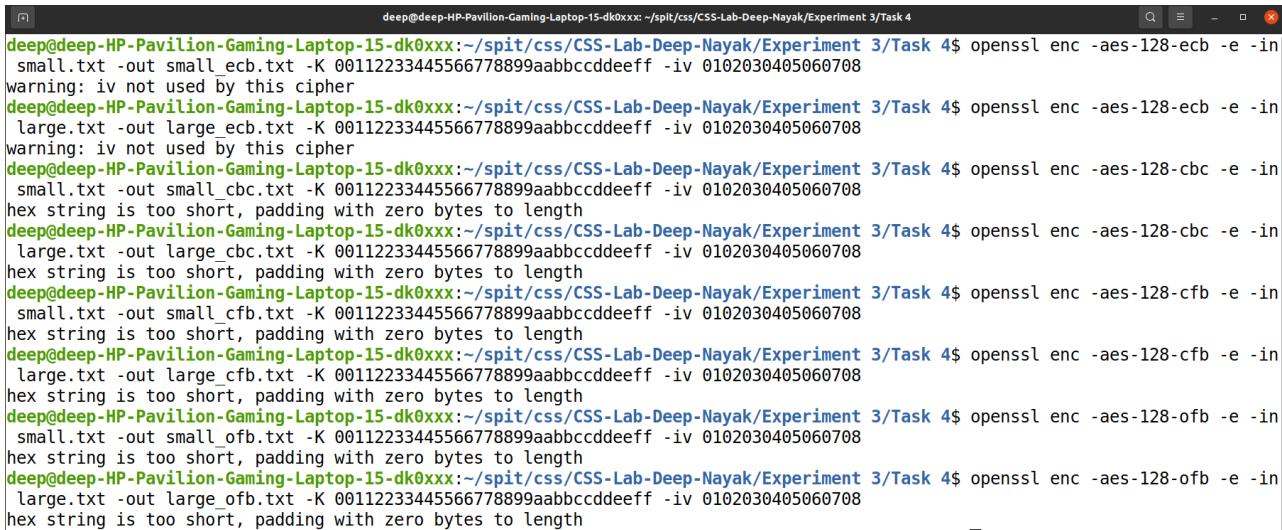

The screenshot shows a terminal window with two tabs: "small.txt" and "large.txt". The "large.txt" tab is active, displaying the text "1 This is a large file of 32 Bytes". The "small.txt" tab is visible in the background.

```
Task 4 > large.txt
1 This is a large file of 32 Bytes
```

**Fig 4.2**

Encrypting using different Encryption methods

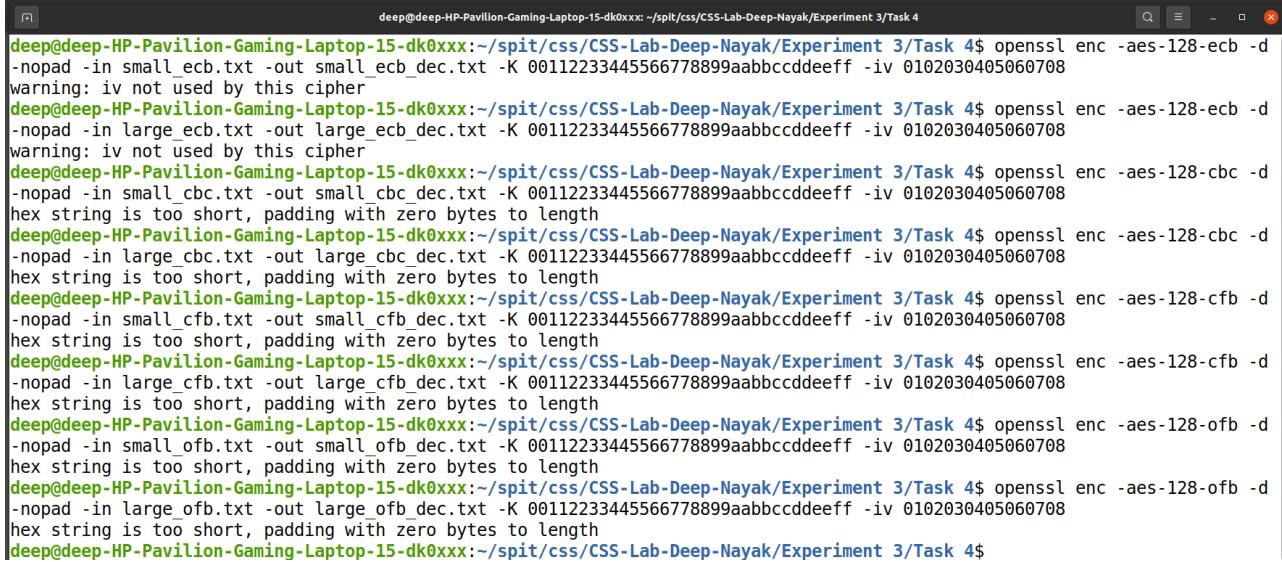

The screenshot shows a terminal window with a series of OpenSSL commands being run. The user is encrypting "small.txt" and "large.txt" using various modes: ECB, CBC, CFB, and OFB, with AES-128 as the cipher. The terminal output shows the command, the file being encrypted, the key (-K), the initialization vector (-iv), and any warnings or errors. The hex string for the encrypted files is also shown.

Fig 4.5

### Observation:

1. The cipher modes which require encryption are CBC and ECB as we can see that for small as well as large text files, it is adding padding and hence increasing the size of the file to be an exact multiple of the block size, which is 16 Bytes for AES.
2. We can confirm that the padding standard is PKCS5 because, whenever a mode which requires padding is used, PKCS5 adds atleast 1 Byte of padding and at most n Bytes of padding where n is the block size. In short, it adds padding to the file so that its size becomes the **next** closest multiple of block size.
3. We can observe this in figure 4.5, as the size of large.txt is increased to 48 Bytes (next multiple of 16 after 32) and 32 Bytes (next multiple of 16 after 20) for small.txt

Fig 4.15

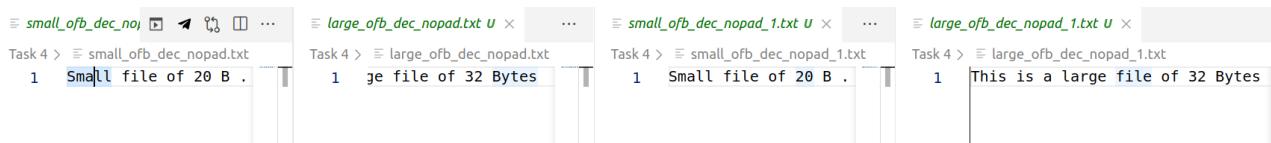

Fig 4.16

## Observation:

1. Padding is not used by CFB and OFB. This is evident from the fact that the plain text is unaffected even if we use nopad option or not.
2. For ECB and CBC mode, while decrypting the cipher text which was encrypted using nopad option, the following is observed:
  - a. If nopad is not used while decrypting, openssl assumes that padding was added while encrypting and hence tries to remove it. This results in loss of data in the decrypted text.
  - b. If nopad is used, openssl does not try to remove the padding and since it was not added while encrypting, the original text is retrieved after decryption.

## Task 5: Programming using the Crypto Library

So far, we have learned how to use the tools provided by openssl to encrypt and decrypt messages. In this task, we will learn how to use openssl's crypto library to encrypt/decrypt messages in programs.

OpenSSL provides an API called EVP, which is a high-level interface to cryptographic functions. Although OpenSSL also has direct interfaces for each individual encryption algorithm, the EVP library provides a common interface for various encryption algorithms. To ask EVP to use a specific algorithm, we simply need to pass our choice to the EVP interface. A sample code is given in [http://www.openssl.org/docs/crypto/EVP\\_EncryptInit.html](http://www.openssl.org/docs/crypto/EVP_EncryptInit.html). Please get yourself familiar with this program, and then do the following exercise.

You are given a plaintext and a ciphertext, and you know that aes-128-cbc is used to generate the ciphertext from the plaintext, and you also know that the numbers in the IV are all zeros (not the ASCII character '0'). Another clue that you have learned is that the key used to encrypt this plaintext is an English word shorter than 16 characters; the word that can be found from a typical English dictionary. Since the word has less than 16 characters (i.e. 128 bits), space characters (hexadecimal value 0x20) are appended to the end of the word to form a key of 128 bits. Your goal is to write a program to find out this key. You can download a English word list from the Internet. We have also linked one on the web page of this lab. The plaintext and ciphertext is in the following:

Plaintext (total 21 characters): This is a top secret. Ciphertext (in hex format):  
8d20e5056a8d24d0462ce74e4904c1b5

13e10d1df4a2ef2ad4540fae1ca0aaf9

Note 1: If you choose to store the plaintext message in a file, and feed the file to your program, you need to check whether the file length is 21. Some editors may add a special character to the end of the file. If that happens, you can use the ghex tool to remove the special character.

Note 2: In this task, you are supposed to write your own program to invoke the crypto library. No credit will be given if you simply use the openssl commands to do this task.

Note 3: To compile your code, you may need to include the header files in openssl, and link to openssl libraries. To do that, you need to tell your compiler where those files are. In your Makefile, you may want to specify the following:

### Crypto Encryption/PV

```
INC=/usr/local/ssl/include/  
LIB=/usr/local/ssl/lib/
```

all:

```
gcc -I$(INC) -L$(LIB) -o enc yourcode.c -lcrypto -ldl
```

Code:

```
from Crypto.Cipher import AES
from Crypto.Util.Padding import pad

plain_text = b"This is a top secret."
cipher_hex = "8d20e5056a8d24d0462ce74e4904c1b513e10d1df4a2ef2ad4540fae1ca0aaf9"

result_k = []
file = open('words.txt', 'r')
lines = file.readlines()
words = [str.strip(line) for line in lines]
for word in words:
    if len(word) >= 16:
        continue
    word = word.lower()
    key = word.encode() + b' '*(16-len(word))
    cipher = AES.new(key, AES.MODE_CBC, iv=bytes.fromhex('0'*32))
    ciphertext = cipher.encrypt(pad(plain_text, AES.block_size))
    is_matched = "NOT MATCHED"
    if bytes.hex(ciphertext) == cipher_hex:
        is_matched = "MATCHED"
        result_k.append(word)
print(word, bytes.hex(ciphertext), is_matched)
print("\n\nResulting Key:", result_k)
```

Fig 5.2

## **Conclusion:**

1. AES, DES are symmetric key algorithms using the same keys to encrypt and decrypt the data. ARIA and Camellia are modern encryption algorithms at par with AES and contain more rounds of computation, substitution and permutation before giving the final result.
2. ECB mode of encryption is the weakest form of encryption in comparison to CBC, CFB and OFB. If it is used to encrypt an image, an outline of the main contents of the image is still visible in the encrypted image.
3. ECB and CBC use padding while encryption while the other two don't. This proves that ECB and CBC are block ciphers while CFB and OFB are stream ciphers. I could also verify that openssl uses PKCS5 standard for padding as it adds padding till the file size becomes the next closest multiple of the block size.
4. I learned how different modes react to a corrupted bit of a cipher text. The best decryption in such a case is provided by OFB where only the corrupted bit of cipher text is affected while encrypting.
5. I could conclude from this experiment that, If we know the plaintext, ciphertext and iv, I can easily find the key using brute force method. In this case, we tried out each word with less than 16 characters from the dictionary and found the key to be "median" as seen in figure 5.2.
